Write an ALP that will taken in a single numeric input between 0 - 9 from the user without echo. (You can assume that the user will enter only numbers). The ALP should compare the character number entered by the user in contents of the two files **a.txt** and **b.txt** (for e.g. if the user enters 3 – the ALP should compare the 3rd character in a.txt and b.txt) and if they are equal should display "***equal***" else display "***not equal***" on the screen. You can assume that the 2 files **a.txt** and **b.txt** will have more than 10 characters and is already available in /bin folder.
